

MySQL In Docker

We will use different databases through the class and to keep it easy to manage on your local machines we will be using containerization technology (Podman/Docker).

Windows

Docker Desktop

Before you install you **MUST** have virtualization enabled at the BIOS level if you don't know how to enable this please do not go into your BIOS alone you can break your machine. [Download Docker Desktop](#) allow it to install and reboot. After reboot it will install WSL automatically.

Setting up MySQL for Docker

Download the Image

```
$ docker pull mysql:latest
```

See if it is now downloaded run the following command. You should see a list of images.

```
$ docker images
```

Now run the following command to install the image into docker. **Make sure** you change the **strong_password** to something you won't forget (mine is just 'root'). You may have to change the port.

```
$ docker run -d --name test-mysql -e MYSQL_ROOT_PASSWORD=strong_password -p 3306:3306 mysql
```

You should now

Linux / MacOS

I use [Podman](#) on Fedora since it is a drop in replacement for Docker and it is more FOSS than Docker. Just install it (you can also install a GUI called Podman Desktop). For each command where it says "docker" just put "podman" ie. **docker pull mysql:latest** turns into **podman pull mysql:latest**

Viewing the DB

You might want to download a tool to view your database. JetBrains has a GUI tool built in but if you want a standalone tool you can download [MySQL Workbench](#) or [DBeaver Community](#).
